Continuous polymerization apparatus including a first reactor of a complete mixing type and a second reactor of a complete mixing type (10, 20). Each of the reactors (10, 20) is provided with a supply port (11a, 21a), an effluent port (11b, 21b), and a temperature detecting means (T) for detecting a temperature in the reactor, wherein the supply port (11a) of the first reactor (10) is connected to the supply sources (1, 3) of a raw material monomer and a polymerization initiator, and the effluent port (11b) of the first reactor is connected through a connection line (15) to the supply port (21a) of the second reactor (20). Connection line (15) is combined with a secondary line (15') for supplying a raw material monomer at a combining part (M) located between the effluent port (11b) of the first reactor (10) and the supply port (21a) of the second reactor (20).

CONTINUOUS POLYMERIZATION APPARATUS AND PROCESS FOR PRODUCING POLYMER COMPOSITION

This application is a National Stage of International Application No. PCT/JP2013/056205 filed Feb. 28, 2013, claiming priority to and the benefit of Japanese Patent Application No. 2012-64755, filed Mar. 22, 2012, the entire contents of which are incorporated herein by reference.

TECHNICAL FIELD

The present invention relates to a continuous polymerization apparatus, i.e. an apparatus for continuously conducting a polymerization. Additionally, the present invention relates to a process for producing polymer composition which is conducted by using such continuous polymerization apparatus.

BACKGROUND ART

Resin compositions such as methacrylic ester polymers are produced by continuous polymerization in which a raw material monomer, a polymerization initiator and so on are continuously supplied to a reactor to be polymerized. As such continuous polymerization processes, there are known a continuous solution polymerization process using a solvent (or a dispersion medium, which also applies hereinafter) to conduct continuous polymerization, and a continuous bulk polymerization process using no solvent to conduct continuous polymerization.

In general, a continuous solution polymerization process is not efficient since use of a solvent causes a low productivity. In contrast, a continuous bulk polymerization process has an advantage of being able to produce a polymer composition efficiently since the polymerization is conducted without using a solvent. Practically, the continuous bulk polymerization, however, has various problems compared with the continuous solution polymerization, such as that reaction control is difficult due to high viscosity of a reaction mixture, and when an inner surface of a reactor is cooled to remove heat from a reaction system, this degrades quality of a polymer composition and thus of a resin composition obtained therefrom. Therefore, a process is proposed which uses a reactor of a complete mixing type, fully fills the reactor with liquid to exclude a gas phase part therefrom, and conducts continuous bulk polymerization under an adiabatic condition with no heat transfer to or from the outside (Patent Literature 1). Further, in order to assure such adiabatic condition, a continuous polymerization apparatus is proposed which controls a supply amount of a raw material monomer and a supply amount of a polymerization initiator so as to make a temperature in the reactor equal to a setting temperature of an outer surface of the reactor (Patent Literature 2).

SUMMARY OF INVENTION

In recent years, applications of resin compositions such as methacrylic ester polymers has been expanded furthermore, a

demand is increasing for more efficiently producing a polymer composition with high quality (for example, a polymer composition having superior properties such as heat resistance and thermal stability, and less immixed with impurities). However, it has been proved that the conventional continuous polymerization apparatus (Patent Literatures 1 and 2) are not always sufficient to meet the demand.

The purpose of the present invention is to provide a novel continuous polymerization apparatus and a process for producing a polymer composition wherein the process can be conducted by using such continuous polymerization apparatus and more efficiently produce the polymer composition suitable for producing a resin composition with high quality.

The inventors considered using at least two reactors of a complete mixing type in combination to conduct continuous polymerization. As to a continuous solution polymerization process, apparatuses having two stages of reactors are known, such as that the most part of polymerization is conducted in the former reactor and the polymerization is completed in the latter reactor while removing a polymerization initiator and the like therefrom (Patent Literature 3); and that polymerization is conducted to some extent in the former reactor and a solvent is added to the latter reactor to conduct polymerization (Patent Literature 4). In such apparatuses, however, removal of heat from a reaction system is conducted by reflux cooling (a raw material monomer or the like in the reactor is evaporated to be taken out of the reactor, and it is returned to the reactor again after subjected to cold condensation). Especially, in a case of conducting the polymerization in a less amount of solvent or with a high polymerization ratio in order to increase a productivity, a viscosity of a mixture in the reaction system becomes high, this makes the local or rapid cooling of the reaction system arise more easily, which makes the adhering and growing of the gel on the inner surface of the reactor prominent. As a result, there is a problem such as that gelled substance is immixed into a resultant polymer composition as impurities. On the other hand, as to a continuous solution polymerization process, a process is proposed which uses two stages of reactors, and set an average residence time in these reactors within the range given based on a half-life of a polymerization initiator (Patent Literature 5). In such apparatuses used in this process, however, removal of heat from a reaction system is conducted by using a jacket provided to an outer surface of the reactor. Especially, in a case of conducting the polymerization in a less amount of solvent or with a high polymerization ratio in order to increase a productivity, the local or rapid cooling by using the jacket provided to an outer surface of the second reactor is required for maintaining temperature in the first reactor and the second reactor at the same temperature to increase a polymerization ratio in the second reactor, which makes adhering and growing of the gel on an inner surface of the reactor. As a result, the problem that gelled substance is immixed into a polymer composition as impurities cannot be solved, and quality of a resultant resin is not always sufficient. The inventors have considered earnestly on a novel continuous polymerization apparatus which can more efficiently produce a polymer composition suitable for producing a resin composition with high quality, and finally completed the present invention.

The present invention provides the following [1] to [13].

[1] A continuous polymerization apparatus which comprises, at least, a first reactor and a second reactor which are of a complete mixing type,
wherein each of the reactors is provided with a supply port, an effluent port, and a temperature detecting means for detecting a temperature in the reactor,

the supply port of the first reactor is connected to supply sources of a raw material monomer and a polymerization initiator,

the effluent port of the first reactor is connected through a connection line to the supply port of the second reactor, and

the connection line is combined with a secondary line for supplying a raw material monomer at a combining part located between the effluent port of the first reactor and the supply port of the second reactor.

[2] The continuous polymerization apparatus according to the above [1], wherein the secondary line is connected to a source of the raw material monomer, and at least one of said source and said secondary line is provided with a temperature regulating means.

[3] The continuous polymerization apparatus according to the above [1] or [2], wherein the connection line is provided with a cooling means.

[4] The continuous polymerization apparatus according to any one of the above [1]-[3], wherein the connection line is provided with a mixing means between the combining part and the supply port of the second reactor.

[5] The continuous polymerization apparatus according to any one of the above [1]-[4], wherein the effluent port of each of the reactors is placed at the top of the reactor.

[6] The continuous polymerization apparatus according to any one of the above [1]-[5], wherein the supply port of the second reactor or another supply port provided to the second reactor is connected to a supply source of an additional polymerization initiator.

[7] The continuous polymerization apparatus according to any one of the above [1]-[6], wherein the first reactor and the second reactor are used for conducting a continuous bulk polymerization.

[8] A process for producing a polymer composition by using the continuous polymerization apparatus according to any one of the above [1]-[7] which comprises:

a first polymerization step of continuously supplying a raw material monomer and a polymerization initiator from the supply sources of the raw material monomer and the polymerization initiator to the first reactor through the supply port of the first reactor to be subjected to continuous polymerization in the first reactor, and continuously taking a resultant intermediate composition from the effluent port of the first reactor,

an intermediate cooling step of continuously cooling the intermediate composition by adding a raw material monomer supplied from the secondary line to the intermediate composition during transport of the intermediate composition from the effluent port of the first reactor to the supply port of the second reactor through the connection line, and

a second polymerization step of continuously supplying the cooled intermediate composition to the second reactor through the supply port of the second reactor to be further subjected to continuous polymerization in the second reactor, and continuously taking a resultant polymer composition from the effluent port of the second reactor.

[9] The process for producing a polymer composition according to the above [8], wherein a temperature of the intermediate composition in the supply port of the second reactor is 5-80° C. lower than a temperature of the intermediate composition in the effluent port of the first reactor.

[10] The process for producing a polymer composition according to the above [8] or [9], wherein a flow rate ratio of the intermediate composition taken out of the effluent port of the first reactor to the connection line and the raw material monomer supplied from the secondary line to the connection line is within a range from 0.995:0.005 to 0.5:0.5.

The process for producing a polymer composition according to any one of the above [8]-[10], wherein a temperature of the raw material monomer supplied from the secondary line to the connection line is from -40 to 30° C.

[12] The process for producing a polymer composition according to any one of the above [8]-[11], wherein a temperature in the first reactor detected by the temperature detecting means of the first reactor and a temperature in the second reactor detected by the temperature detecting means of the second reactor are within a range from 120 to 150° C.

[13] A molded article which is prepared from the polymer composition produced by the process according to any one of the above [8]-[12].

According to the present invention, there is provided a novel continuous polymerization apparatus. Additionally, according to the present invention, there is provided a process for producing a polymer composition wherein the process can be conducted by using such continuous polymerization apparatus and more efficiently produce the polymer composition suitable for obtaining a resin composition with high quality.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 shows a schematic view of a continuous polymerization apparatus in one embodiment of the present invention.

FIG. 2 shows a schematic view of a continuous polymerization apparatus in which a jacket is provided to the connection line in the embodiment of FIG. 1.

FIG. 3 shows a schematic view of a continuous polymerization apparatus in which a cooler is provided to the connection line in the embodiment of FIG. 1.

DESCRIPTION OF EMBODIMENTS

A continuous polymerization apparatus of the present invention comprises at least two reactors, and continuous polymerization such as any of continuous bulk polymerization and continuous solution polymerization is conducted in each of the reactors. The continuous polymerization apparatus of the present invention will be understood as a continuous bulk polymerization apparatus when continuous bulk polymerization is conducted in all of reactors, and understood as a continuous solution polymerization apparatus when continuous solution polymerization is conducted in all of the reactors. However, the continuous polymerization apparatus of the present invention is not limited thereto, but may be those wherein continuous bulk polymerization is conducted in one reactor (e.g. at least one former reactor) and continuous solution polymerization is conducted in another reactor (e.g. at least one latter reactor).

Hereinafter, one embodiment of the present invention will be described in detail with reference to FIGS. 1-3.

A continuous polymerization apparatus in this embodiment comprises, at least, a first reactor 10 and a second reactor 20. These reactors 10 and 20 are both a reactor of a complete mixing type, and used to conduct continuous bulk polymerization in this embodiment.

More specifically, the first reactor 10 is provided with a supply port 11a and an effluent port 11b, and preferably further provided with a jacket 13 as a temperature regulating means for regulating a temperature of an outer surface of the reactor and a stirrer 14 for stirring contents therein. Similarly, the second reactor 20 is provided with a supply port 21a and an effluent port 21b, and preferably further provided with a jacket 23 surrounding an outer surface of the reactor as a temperature regulating means for regulating a temperature of the outer surface of the reactor and a stirrer 24 for stirring contents therein. The effluent ports 11b and 21b are located at a top of each of the reactors in this embodiment, but not limited thereto. On the other hand, the supply ports 11a and 21a may be generally located at an appropriate position of a lower part of each of the reactors, although this embodiment is not limited thereto. Each of these reactors 10 and 20 may be provided with a temperature sensor T as a temperature detecting means for detecting a temperature in the reactor.

The first reactor 10 and the second reactor 20 may have the same or different inner volume from each other. Making the inner volume of the first reactor and the inner volume of the second reactor different from each other, it is possible to effectively differentiate between the first reactor 10 and the second reactor 20 in an average residence time.

The stirrers 14 and 24 are a member for substantially attaining a complete mixing condition in the reactors. These stirrers may have any appropriate stirring blade(s), for example, may have blades of MIG impeller, MAXBLEND impeller (registered trademark, manufactured by Sumitomo Heavy Industries, Ltd.), paddle impeller, double helical ribbon impeller, FULLZONE impeller (registered trademark, manufactured by Kobelco Eco-Solutions Co., Ltd.) and so on. In order to increase stirring effect in the reactor, it is preferable to provide the reactor with a baffle(s). However, this embodiment is not limited thereto, but may have any appropriate configuration in place of the stirrers 14 and 24 as long as a complete mixing condition can be substantially attained in the reactors.

In general, the reactors 10 and 20 are more preferable when they have a higher stirring efficiency. However, in view of

6

avoiding the reactors from being added with an unnecessary amount of heat by the stirring operation, it is preferable that a power of stirring is not more than necessary. The power of stirring is not particularly limited, but preferably 0.5 to 20 kW/m³, and more preferably 1 to 15 kW/m³. As a viscosity of the reaction system becomes higher (or a content ratio of a polymer in the reaction system becomes higher), it is preferable to set the power of stirring at a larger level.

As shown in the drawings, the supply port 11a of the first reactor 10 is connected through a raw material supply line 9 to a raw material monomer tank (a supply source of a raw material monomer) 1 and a polymerization initiator tank (a supply source of a polymerization initiator and, if necessary, of a raw material monomer) 3 via pumps 5 and 7, respectively. In this embodiment, the supply sources of the raw material monomer and the polymerization initiator to the first reactor 10 are the raw material monomer tank 1 and the polymerization initiator tank 3, respectively. However, the number of the supply sources of the raw material monomer and the polymerization initiator, the forms of the raw material monomer and the polymerization initiator (in a case of a mixture, for example, a composition thereof) and so on are not particularly limited as long as the raw material monomer and the polymerization initiator can be supplied to the first reactor 10, appropriately. Although it is not necessary for this embodiment, but another supply port 11c may be provided to the first reactor 10 and this supply port 11c may be connected to the polymerization initiator tank 3 via the pump 7 as shown by a dotted line in FIG. 1. The effluent port 11b of the first reactor 10 is connected to the supply port 21a of the second reactor 20 through a connection line 15. The effluent port 21b of the second reactor 20 is linked up to an effluent line 25. Thus, the first reactor 10 and the second reactor 20 are connected in series. There is preferably no pump on the connection line 15 between the effluent port 11b of the first reactor 10 and the supply port 21a of the second reactor 20.

This connection line 15 is combined (or merges) with a secondary line 15' at a combining (or merging) part M located between the effluent port 11b of the first reactor 10 and the supply port 21a of the second reactor 20. The secondary line 15' is a line for supplying a raw material monomer to the connection line 15 and connected to the raw material monomer tank (a supply source of the raw material monomer) 2 via a pump 6. In this embodiment, the supply source of the raw material monomer (and any other components such as a chain transfer agent, if necessary) to the connection line 15 is the raw material monomer tank 2. However, the number of the supply source of the raw material monomer, the form of the raw material monomer (in a case of a mixture, for example, a composition thereof) and so on are not particularly limited as long as the raw material monomer can be supplied to the connection line 15 from the secondary line 15', appropriately. Such configuration enables that the raw material monomer is supplied to the connection line 15 from the secondary line 15' depending on, for example, the temperature in the first reactor 10 and/or the second reactor 20 and so on. Since the first reactor is provided with the temperature sensor T as the temperature detecting means for detecting the temperature in the first reactor 10 as described in the above, the pump 6 can be controlled so as to make the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 at a temperature (for example, in a predetermined range of temperature) lower than the temperature in the first reactor 10 detected by this temperature sensor T.

It is not necessary for the present invention, but the second reactor 20 is preferably connected to a polymerization initiator tank (a supply source of an additional polymerization

7

initiator and, if necessary, of a raw material monomer) 17 via a pump 19. In this embodiment, the supply source(s) of the additional polymerization initiator is the polymerization initiator tank 17, but the number of the supply source(s) of the additional polymerization initiator, the form of the polymerization initiator (in a case of a mixture, for example, a composition thereof) and so on are not particularly limited as long as the additional polymerization initiator can be supplied to the second reactor 20, appropriately. In a case where the polymerization initiator tank 17 and the pump 19 are present, the supply port 21a of the second reactor 20 may be connected to the polymerization initiator tank 17 via the pump 19 from any point on the connection line 15 as shown in FIG. 1 (preferably, from a point downstream of the combining part M as shown in FIG. 1), or the second reactor 20 may be provided with another supply port 21c so that this supply port 21c is connected to the polymerization initiator tank 17 via the pump 19 as shown by, for example, a dotted line in FIG. 1.

The pumps 5-7 and, if present, the pump 19 are not particularly limited, but preferably pumps being able to set flow rates from the raw material monomer tanks 1, 2 and the polymerization initiator tank 3 and a flow rate from the polymerization initiator tank 17, if present, at constant values. More specifically, multiple reciprocating pumps are preferred, and more preferred are pulsation-free controlled-volume pumps such as a duplicate pulsation-free controlled-volume pump and a triplex pulsation-free controlled-volume pump. By using these, it is possible to control a supply amount (or a supply flow rate, which also applies hereinafter) of the raw material monomer and the polymerization initiator to the first reactor 10, a supply amount of the raw material monomer to the connection line 15 and, if necessary, an additional supply amount of the polymerization initiator (or the raw material monomer and the polymerization initiator) to the second reactor 20.

Further, the connection line 15 which connects the effluent port 11b of the first reactor 10 to the supply port 21a of the second reactor 20 may be provided with, for example, a jacket 16 (shown by hatching in FIG. 2) surrounding a part of or the whole of an outer surface of the connection line 15, a cooler 40 with which a part of the connection line 15 is replaced as shown in FIG. 3, and/or a trace pipe through which a cooling medium passes (the connection line provided with the jacket is understood as a double pipe), as a cooling means being able to cool, at least partially, the connection line 15. By supplying the raw material monomer from the secondary line 15' to the connection line 15 in combination with cooling of the connection line 15 by the cooling means, depending on the temperature of the first reactor 10 and/or the second reactor 20 and so on, the temperature of the connection line 15 (more specifically, the temperature in the inside of the connection line) can be more lower. As mentioned above, since the first reactor 10 is provided with the temperature sensor T as a temperature detecting means for detecting a temperature in the first reactor 10, the jacket or the cooler 40 (a cooling means) of the connection line 15 can be controlled so that the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 is lower than the temperature in the first reactor 10 which is detected by the temperature sensor T. The cooler 40 is provided to the connection line 15 in any appropriate configuration, for example, at a location either upstream from the combining part M as shown in FIG. 3 or downstream from the combining part, and it is preferably provided to the connection line 15 at a location upstream from the combining part. The line parts other than the cooler 40 of the connection line 15 may be covered with a lagging to retain heat (not shown in the drawings), or a jacket (not shown in

8

FIG. 3) surrounding an outer surface of the connection line 15 may be used in combination for cooling.

Further, it is not necessary for this embodiment, but the connection line 15 is preferably provided with a mixing means in that a temperature distribution in the connection line 15 can be more homogenized, and an occlusion of the connection line 15 by an intermediate composition (hereinafter described) which flows through in the connection line 15 can be suppressed. The mixing means is preferably provided to the connection line 15 at a location downstream from the combining part M, i.e. between the combining part M and the supply port 21a of the second reactor 20 in view of enhancing a cooling efficiency. Examples of the mixing means include, for example, a static mixer, a dynamic mixer, and so on. Among them, the static mixer is preferable. The static mixer is a mixer without a drive member, and is provided to the connection line 15 in any appropriate configuration. For example, in FIGS. 1-2, the static mixer may be inserted into the downstream portion of the connection line 15 from the combining part M at an appropriate position, or a part of or the whole of the downstream portion of the connection line 15 from the combining part M may be replaced with the static mixer constituting the line. In FIG. 3, the static mixer can be inserted into the downstream portion of the connection line 15 from the combining part M (a line part other than the cooler 40, if present) at an appropriate position, or a part of or the whole of the downstream portion of the connection line 15 from the combining part M (the line part other than the cooler 40, if present) may be replaced with the static mixer constituting the line. Examples of the static mixer include, for example, "Sulzer mixer" (manufactured by Sulzer Chemtech Ltd.) and so on. For example, Sulzer mixer of SMX type, SMI type, SMV type, SMF type, or SMXL type can be used. In a case where the polymerization initiator tank 17 is connected to the connection line 15 via the pump 19, it is preferred that the mixing means is provided to a downstream portion of the connection line 15 from any of the combining part M and a combining part with the supply line connected to the polymerization initiator tank 17.

Further, in the embodiment shown in FIG. 3, a cooler which combines a cooling means and a mixing means may be provided as the cooler 40. Examples of the cooler 40 which combines a cooling means and a mixing means include a cooler having a dynamic mixing function and a cooler having a static mixing function. Examples of the cooler having a dynamic mixing function include, for example, a screw mixer being able to cool a cylinder and so on. Examples of the cooler having a static mixing function include, for example, a heat exchanger with a built-in static mixer and so on. As the heat exchanger with a built-in static mixer, preferably, Sulzer mixer of SMR type (manufactured by Sulzer Chemtech Ltd.) is used in view of having a large a heat-transfer area and being able to provide a high cooling capacity. In a case where the heat exchanger with a built-in static mixer is used as the cooler 40, a part of or the whole of the connection line 15 may be replaced with the heat exchanger with a built-in static mixer constituting the line.

As described in the above with reference to FIG. 1, the secondary line 15' is connected to the raw material monomer tank (the supply source of the raw material monomer and, if present, other component(s) such as a chain transfer agent) 2 via the pump 6. It is preferable that at least one of the raw material monomer tank 2 and the secondary line 15' is provided with a temperature regulating means. The raw material monomer tank 2 may be provided with, for example, a jacket covering at least partially an outer surface of the raw material monomer tank 2 as the temperature regulating means, and

such temperature regulating means can regulate a temperature of the raw material monomer in the raw material monomer tank 2. In a case where the monomer tank 2 is provided with the jacket, the monomer tank 2 is preferably further provided with a stirring and/or mixing means for stirring the raw material monomer in the raw material monomer tank 2 in view of more effective temperature regulation. Further, the secondary line 15' may be provided with, for example, a jacket covering at least partially an outer surface of the secondary line 15', a heater/cooler with which a part of the secondary line 15' is replaced, and/or a trace pipe through which a cooling medium passes (the secondary line provided with the jacket is understood as a double pipe), as the temperature regulating means, and such temperature regulating means can regulate a temperature of the raw material monomer flowing through the secondary line 15'. As the heater/cooler, a heater/cooler having both a heating/cooling means and a mixing means, more specifically, ones having a function of dynamic mixing (e.g. screw mixer being able to heat/cool its cylinder) and ones having a function of static mixing (e.g. heat exchanger with a built-in static mixer) may be used. By the use of the temperature regulating means provided to the raw material monomer tank 2 and/or the secondary line 15' as in the above, the temperature of the raw material monomer supplied from the secondary line 15' to the connection line 15 can be regulated. The temperature regulating means provided to the raw material monomer tank 2 and/or the secondary line 15' can regulate the temperature of the raw material monomer supplied to the connection line 15, depending on the temperature of the first reactor 10 and/or the second reactor 20 and so on. As mentioned above, since the first reactor 10 is provided with the temperature sensor T as a temperature detecting means for detecting the temperature in the first reactor 10, the temperature regulating means provided to the raw material monomer tank 2 and/or the secondary line 15' can be controlled so that the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 is lower than the temperature in the first reactor 10 which is detected by this temperature sensor T. However, examples of the temperature regulating means provided to the raw material monomer tank 2 and/or the secondary line 15' and a method for regulating the temperature of the raw material monomer supplied to the connection line 15 are not limited thereto.

It is preferable that each of the members described in the above with reference to FIG. 1 is appropriately connected to a control means described below (not shown in the drawings) and construct the whole so as to enable the control means to control their operations. Thereby, in order to make the temperature of the outer surface of the reactor set for each of the jackets (temperature regulating means) 13 and 23 correspond to the temperature in the reactor detected by the temperature sensor (temperature detecting means) T with respect to each of the first reactor 10 and the second reactor 20 (in the other words, in order to achieve an adiabatic condition in each of the first reactor 10 and the second reactor 20), the supply amounts of the raw material monomer and the polymerization initiator to the first reactor 10 can be adjusted by the operation of the pumps 5 and 7, or the temperature of the outer surface of the reactor set for the jackets 13 and 23 can be regulated; and also, in a case where the polymerization initiator tank 17 and the pump 19 are present, the additional supply amount of the polymerization initiator (or the raw material monomer and the polymerization initiator) to the second reactor 20 can be adjusted by the operation of the pump 19. Further, in order to achieve the desired polymerization ratio in the second reactor 20 and avoid a polymerization temperature in the second reactor 20 from being too high, it is possible to make

the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 lower than the temperature in the first reactor 10 detected by the temperature sensor (temperature detecting means) T by adjusting the supply amount of the raw material monomer to the connection line with operation of the pump 6. Further in a case where the cooling means is used in combination, the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 can become lower than the temperature in the first reactor 10 detected by the temperature sensor (temperature detecting means) T by adjusting the temperature of the outer surface of the connection line 15 set for the jacket (cooling means) 16 covering the connection line 15 in FIG. 2, and by adjusting a setting temperature of the cooler 40 with which a part of the connection line 15 is replaced in FIG. 3. It is preferable that the temperature in the connection line 15 is actually measured at a place adjacent to the supply port 21a of the second reactor 20, or as the case may be, at other place by a temperature detecting means for detecting the temperature in the connection line 15. However, in some cases, depending on the polymerization reaction conditions in the first reactor 10, due to some causes such as that all of the supplied polymerization initiator is spent, an intermediate composition (hereinafter described) taken from the effluent port 11b does not let the polymerization reaction proceed in the connection line 15, that is, no heat of the polymerization reaction is generated in the connection line 15. In such case, considering the temperature in the connection line 15 adjacent to the effluent port 11b of the first reactor 10 as a substantially same temperature as the temperature in the first reactor 10 detected by the temperature sensor (temperature detecting means) T is allowable. Further, in such case, it is considered that the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 becomes lower than the temperature of the first reactor 10 by supplying the raw material monomer from the secondary line 15' to the connection line 15 and/or by setting the temperature of, if present, the jacket 16 covering the connection line 15 or the temperature of the cooler 40 with which a part of the connection line 15 is replaced at a temperature lower than the temperature in the first reactor 10. In FIG. 3, when the line part other than the cooler 40 of the connection line 15 is provided with a jacket surrounding it, the temperature in the connection line 15 may be adjusted by using the jacket in combination.

The jackets 13 and 23 surround almost the whole of the reactors 10 and 20, respectively to appropriately heat or retain the heat of the reactors 10 and 20 by introducing steam, hot water, organic heat medium or the like from a heat medium supply route (not shown in the drawings). The temperature of the jackets 13 and 23 is able to be appropriately regulated with a temperature or pressure of the heat medium to be introduced. The heat medium introduced into the jackets 13 and 23 is removed from a heat medium discharge route (not shown in the drawings). The temperature and/or pressure of the jackets 13 and 23 are detected by a sensor such as a temperature sensor (not shown in the drawings) located on the heat medium discharge route. The point of location of a sensor such as the temperature sensor is not particularly limited, but it may be located, for example, on the heat medium supply route, or in the jackets 13 and 23. The jacket 16 provided to the connection line 15 as a cooling means in FIG. 2 and the jacket, if present, provided to the raw material monomer tank 2 and/or the secondary line 15' as the temperature regulating means may have the same constitution as that of the jackets 13 and 23. Although the embodiment in FIG. 2 is not limited thereto, the connection line 15 may be typically a double pipe, in which the internal space of the inner pipe is a flow path of

11

an intermediate composition (hereinafter described), the space between the inner pipe and the outer pipe is a flow path of a heat medium (jacket 16).

For the polymerization reaction in the reactors 10 and 20, it is required to proceed at a generally constant temperature in each of the reactors 10 and 20 in view of obtaining a polymer with a constant quality. Therefore, the above described temperature regulating means (jackets 13 and 23) is controlled at a constant temperature which has been set beforehand, so that the temperature inside the reactors 10 and 20 can be maintained respectively at a generally constant temperature.

The setting temperature of the above described temperature regulating means (jackets 13 and 23) is transmitted to a control means described below, to be used as data for determining whether control of the supply flow rate with the monomer supply means (pumps 5 and 6) and/or the initiator supply means (pump 7 and, if present, pump 19) is necessary or not. The setting temperature of the above described temperature regulating means (jackets 13 and 23) can be regulated by controlling the temperature or pressure of the above described heat medium.

Examples of the control means include, for example, a control unit (not shown in the drawings) provided with CPU, ROM, RAM and so on.

The ROM of the control means is a device for storing a program which controls the pumps 5-7 and, if present, the pump 19 and so on. The RAM of the control means is a device for temporary storing data of the temperatures in the reactors 10 and 20 detected by the temperature sensor T, data of the setting temperatures of the jackets 13 and 23, and data of the setting temperature of the jacket 16 or the cooler 40, if present, of the connection line 15 and so on in order to execute the above program.

The CPU of the control means executes the program stored in the ROM based on data such as the data of the temperatures in the reactors 10 and 20 and the data of the setting temperatures of the jackets 13 and 23 stored in the above RAM so that the supply flow rates of the raw material monomer and/or the polymerization initiator to the reactors 10 and 20 is controlled by the monomer supply means (pumps 5 and 6) and/or the initiator supply means (pump 7 and, if present, pump 19). Specifically, with respect to the raw material monomer supplied from the secondary line 15' to the connection 15, the CPU of the control means executes the program stored in the ROM (which may be either a part of the above program or other program than the above program) based on data such as the data of the temperatures in the reactors 10 and 20 and the data of the setting temperature of the jacket 16 or the cooler 40 of the connection line 15 stored in the above RAM, and in the case of actually measuring, the temperature in the connection line 15 at the point adjacent to the supply port 21a of the second reactor 20 or other point, so that the supply flow rate of the raw material monomer from the secondary line 15' to the connection line 15 is controlled by the monomer supply means (pump 6). Also, with respect to the jacket 16 or the cooler 40 which may be provided to the connection line 15 as the cooling means, it is possible by the similar manner in the above to adjust the setting temperature of the jacket 16 or the cooler 40 of the connection line 15.

An example of the control by the control means (control unit) will be described below.

When the temperature in the reactor 10 detected by the temperature sensor T exceeds the setting temperature of the jacket 13 as the temperature regulating means, the CPU executes the program in the ROM to control, for example, the pump 7 so as to decrease the supply flow rate of the polymerization initiator into the reactor 10. When the temperature in

12

the reactor 20 detected by the temperature sensor T exceeds the setting temperature of the jacket 23 as the temperature regulating means, the CPU executes the program in the ROM to control, for example, the pump 6 so as to increase the supply flow rate of the raw material monomer from the secondary line 15' to the connection line 15. Further, in a case where the polymerization initiator tank 17 and the pump 19 are present, when the temperature in the reactor 20 detected by the temperature sensor T exceeds the setting temperature of the jacket 23 as the temperature regulating means during the pump 19 supplies the polymerization initiator to the reactor 20 to conduct the polymerization, the CPU executes the program in the ROM to control, for example, the pump 19 so as to decrease the supply flow rate of the polymerization initiator into the reactor 20. By conducting such control, polymerization heat generated in the reactors 10 and/or 20 can be decreased, and thereby the temperatures in the reactors 10 and/or 20 can be lowered.

On the other hand, when the temperature in the reactor 10 is below the setting temperature of the jacket 13, the CPU executes the program in the ROM to control, for example, the pump 7 so as to increase the supply flow rate of the polymerization initiator into the reactor 10. When the temperature in the reactor 20 is below the setting temperature of the jacket 23, the CPU executes the program in the ROM to control, for example, the pump 6 so as to decrease the supply flow rate of the raw material monomer from the secondary line 15' to the connection line 15. Further, in a case where the polymerization initiator tank 17 and the pump 19 are present, when the temperature in the reactor 20 is below the setting temperature of the jacket 23 during the pump 19 supplies the polymerization initiator to the reactor 20 to conduct the polymerization, the CPU executes the program in the ROM to control, for example, the pump 19 so as to increase the supply flow rate of the polymerization initiator into the reactor 20. By conducting such control, polymerization heat generated in the reactors 10 and/or 20 can be increased, and thereby the temperatures in the reactors 10 and/or 20 can be raised.

For example, when the control over the pumps 6-7 and, if present, the pump 19 for the polymerization reaction in the reactors 10 and 20 results in remarkable decrease in the total supply flow rate into the reactors 10 and 20, it is preferable to not only control the pump 6 so as to decrease the supply flow rate of the raw material monomer and/or control the pump 7 and, if present, the pump 19 so as to decrease the supply flow rate of the polymerization initiator, but also to control the pump 5 so as to increase the supply flow rate of the raw material monomer at the same time.

Further, as another example of the control, the following control is noted. That is, when the temperature in the reactor 10 detected by the temperature sensor T exceeds the setting temperature of the jacket 13 as the temperature regulating means, the pump 5 is controlled to increase the supply flow rate of the raw material monomer, so that the relative supply flow rate of the polymerization initiator into the reactor 10 is decreased. By conducting such control, the temperature in the reactor 10 can also be lowered.

A ratio of the total supply flow rate of the raw material monomer and the supply flow rate of the polymerization initiator can be appropriately set depending on the kind of the polymer generated, the kind of the polymerization initiator used, and so on.

Also, degree of increase or decrease in the supply flow rate of the raw material monomer and/or the supply flow rate of the polymerization initiator can be appropriately set depending on the kind of the polymer generated, the kind of the polymerization initiator used, and so on. However, in a case

13

what is supplied to the reactors 10 and 20 by the initiator supply means is not the polymerization initiator only, but the raw material monomer comprising the polymerization initiator, it is necessary to consider a content ratio of the polymerization initiator in the raw material monomer comprising

polymerization initiator to control the supply flow rate of the polymerization initiator.

Further, as another example of the control, for the pump 6 as the monomer supply means and the jacket 16 or the cooler 40 which may be provided to the connection line 15 as a cooling means, the following control is noted. When the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 is the temperature in the first reactor 10 detected by the temperature sensor T or above, the CPU executes the program in the ROM to control the pump 6 so as to adjust the supply flow rate of the raw material monomer supplied from the secondary line 15' to the connection line 15, and, if present, to control an equipment associated with the jacket 16 or the cooler 40 (not shown in the drawings) so as to adjust a setting temperature of the jacket 16 or the cooler 40 of the connection line 15 at a lower temperature, so that the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 become a lower temperature, preferably 5-80° C. lower temperature, than the temperature in the first reactor 10. The setting temperature of the jacket 16 of the connection line 15 can generally be adjustable by controlling a flow rate and/or temperature of a heat medium flowed in the jacket 16, but not particularly limited thereto. The setting temperature of the cooler 40 of the connection line 15 can generally be adjustable, when a heat exchanger with a built-in static mixer is used as the cooler 40, by controlling a flow rate and/or temperature of a heat medium flowed in the heat exchanger with a built-in static mixer, but not particularly limited thereto.

As a preferable example of the control, the following control can be conducted. When the temperature in the second reactor 20 detected by the temperature sensor T of the second reactor 20 is the temperature in first reactor detected by the temperature sensor T of the first reactor 10 or above, the CPU executes the program in the ROM to appropriately control the pump 6 so as to adjust the supply flow rate of the raw material monomer supplied from the secondary line 15' to the connection line 15 (and thus to the second reactor 20), and in a case of the combination use to control as mentioned above so as to adjust the setting temperature of the jacket 16 or the cooler 40 (and, when the cooler 40 and a jacket are used in combination, the jacket) of the connection line 15, or to control the pumps 5 and 7 and, if present, the pump 19 so as to adjust other flow rate to the reactor 10 and/or the reactor 20, so that the temperature in the connection line 15 adjacent to the supply port 21a of the second reactor 20 become a lower temperature, preferably 5-80° C. lower temperature, than the temperature in the first reactor 10. Thereby the temperature difference between the temperature in the first reactor 10 and the temperature of the second reactor 20 can be reduced. When a polymerization heat is generated in the second reactor 20, for example, due to the presence of the polymerization initiator tank 17 and the pump 19, it is effective to control the pump 6 so as to adjust the supply flow rate of the raw material monomer, and in the case of the combination use to adjust the setting temperature of the jacket 16 or the cooler 40 (and, when the cooler 40 and a jacket are used in combination, the jacket) of the connection line 15.

Additionally, it is not necessary for this embodiment, but a preheater 31 and a devolatilizing extruder 33 may be located downstream of the effluent line 25. There may be a pressure adjusting valve (not shown in the drawings) provided between the preheater 31 and the devolatilizing extruder 33.

14

An extruded object after devolatilization is discharged from a discharge line 35.

As the preheater 31, any appropriate heater can be used as long as it is able to heat a viscous fluid. As the devolatilizing extruder 33, a single or multi screw devolatilizing extruder can be used.

Further, there may be a recovery tank 37 for storing the raw material monomer which is separated and recovered from a volatile component (comprising unreacted raw material, mainly) separated with the devolatilizing extruder 33.

Next, a process for producing a polymer composition conducted by using such apparatus will be described. In this embodiment, a case of conducting continuous polymerization of a methacrylic ester monomer, in the other words, a case of producing a methacrylic ester polymer will be described as an example, although the present invention is not limited thereto.

Preparation

At first, the raw material monomer, the polymerization initiator and so on are prepared.

As the raw material monomer, a methacrylic ester monomer is used in this embodiment.

Examples of the methacrylic ester monomer are

alkyl methacrylate (of which alkyl group has 1 to 4 carbons) alone, or

a mixture of not less than 80% by weight of alkyl methacrylate (of which alkyl group has 1 to 4 carbons) and not more than 20% by weight of other vinyl monomer copolymerizable therewith.

Examples of alkyl methacrylate (of which alkyl group has 1 to 4 carbons) include methyl methacrylate, ethyl methacrylate, n-propyl methacrylate, isopropyl methacrylate, n-butyl methacrylate, t-butyl methacrylate, sec-butyl methacrylate, isobutyl methacrylate, and so on. Among them, methyl methacrylate is preferred. The above described examples of alkyl methacrylate may be used alone or in combination of at least two of them.

Examples of copolymerizable vinyl monomer include monofunctional monomers having one double bond which is radical-polymerizable and multifunctional monomers having two or more double bonds which are radical-polymerizable. More specifically, examples of the monofunctional monomers having one double bond which is radical-polymerizable include, for example, methacrylic esters such as benzyl methacrylate and 2-ethylhexyl methacrylate (except for the above described alkyl methacrylate (of which alkyl group has 1 to 4 carbons)); acrylic esters such as methyl acrylate, ethyl acrylate, propyl acrylate, butyl acrylate, and 2-ethylhexyl acrylate; unsaturated carboxylic acids or acid anhydrides thereof such as acrylic acid, methacrylic acid, maleic acid, itaconic acid, maleic acid anhydride, and itaconic acid anhydride; hydroxy group-containing monomers such as 2-hydroxyethyl acrylate, 2-hydroxypropyl acrylate, monoglycerol acrylate, 2-hydroxyethyl methacrylate, 2-hydroxypropyl methacrylate, and monoglycerol methacrylate; nitrogen-containing monomers such as acrylamide, methacrylamide, acrylonitrile, methacrylonitrile, diacetoneacrylamide, and dimethylaminoethyl methacrylate; epoxy group-containing monomers such as allyl glycidyl ether, glycidyl acrylate, and glycidyl methacrylate; styrene based monomers such as styrene and α -methylstyrene. Examples of the multifunctional monomers having two or more double bonds which are radical-polymerizable include, for example, diesters of unsaturated carboxylic acids and glycols such as ethylene glycol dimethacrylate, and butane diol dimethacrylate; unsaturated carboxylic acid alkenyl esters such as allyl acrylate, allyl

15

methacrylate, and allyl cinnamate; polybasic acid polyalkenyl esters such as diallyl phthalate, diallyl maleate, triallyl cyanurate, and triallyl isocyanurate; esters of unsaturated carboxylic acids and polyalcohols such as trimethylolpropane triacrylate; and divinylbenzene. The above described examples of copolymerizable vinyl monomer may be used alone or in combination of at least two of them.

The raw material monomer is supplied dividedly to the first reactor **10** and to the second reactor **20**. To the second reactor **20**, the raw material monomer is supplied through the connection line **15** from the secondary line **15'**.

As the polymerization initiator, for example, a radical initiator is used in this embodiment.

Examples of the radical initiator include azo compounds such as azobisisobutyronitrile, azobisdimethylvaleronitrile, azobiscyclohexanenitrile, 1,1'-azobis(1-acetoxy-1-phenylethane), dimethyl 2,2'-azobisisobutylate, and 4,4'-azobis-4-cyanovaleric acid; organic peroxides such as benzoyl peroxide, lauroyl peroxide, acetyl peroxide, caprylyl peroxide, 2,4-dichlorobenzoyl peroxide, isobutyl peroxide, acetyl cyclohexylsulfonyl peroxide, t-butyl peroxyisovalate, t-butyl peroxyneodecanoate, t-butyl peroxyneohexanoate, t-butyl peroxy-2-ethylhexanoate, 1,1-di(t-butylperoxy)cyclohexane, 1,1-di(t-butylperoxy)-3,3,5-trimethylcyclohexane, 1,1-di(t-hexylperoxy)-3,3,5-trimethylcyclohexane, isopropyl peroxydicarbonate, isobutyl peroxydicarbonate, s-butyl peroxydicarbonate, n-butyl peroxydicarbonate, 2-ethylhexyl peroxydicarbonate, bis(4-t-butylcyclohexyl)peroxydicarbonate, t-amyl peroxy-2-ethylhexanoate, 1,1,3,3-tetramethyl butyl peroxy-ethylhexanoate, 1,1,2-trimethyl propyl peroxy-2-ethylhexanoate, t-butyl peroxy isopropyl monocarbonate, t-amyl peroxy isopropyl monocarbonate, t-butyl peroxy-2-ethylhexyl carbonate, t-butyl peroxy allyl carbonate, t-butyl peroxy isopropyl carbonate, 1,1,3,3-tetramethyl butyl peroxy isopropyl monocarbonate, 1,1,2-trimethyl propyl peroxy isopropyl monocarbonate, 1,1,3,3-tetramethyl butyl peroxy isononate, 1,1,2-trimethyl propyl peroxy-isononate, and t-butyl peroxybenzoate.

These polymerization initiators may be used alone or in combination of at least two of them.

The polymerization initiator is selected depending on the kinds of the polymer to be produced and the raw material monomer used. For example, although the present invention is not particularly limited, as the polymerization initiator (radical initiator), those of which τ/θ (—) is, for example not more than 0.1, preferably not more than 0.02, more preferably not more than 0.01 can be used, wherein τ (second) represents a half-life of the polymerization initiator at the polymerization temperature, and θ (second) represents an average residence time in a reactor. When the value of τ/θ is not more than the above value, a polymerization reaction can be effectively initiated because the polymerization initiator is sufficiently decomposed (thus, generating a radical) in a reactor. Further, since the polymerization initiator is sufficiently decomposed in the first reactor **10**, it can be effectively suppressed to decompose the polymerization initiator to initiate polymerization in the connection line **15**, as a result, it can be effectively avoided to increase a viscosity of the intermediate composition during it passes through the connection line **15**, and/or to occlude the connection line **15** by the intermediate composition.

The supply amount of the polymerization initiator (radical initiator) is not particularly limited, but generally 0.001 to 1% by weight with respect to the raw material monomer (the raw material monomer eventually supplied to the reactors **10** and **20**). In a case where the polymerization initiator tank **17** and the pump **19** are present in addition to the polymerization

16

initiator tank **3** and the pump **7**, the polymerization initiator can be supplied separately into the first reactor **10** and the second reactor **20**. When the polymerization initiator tank **17** supplies the mixture of the raw material monomer and the polymerization initiator to the second reactor **20** by the pump **19**, the total supply amount of the polymerization initiator supplied to the reactor **10** and the reactor **20** is made within the above range with respect to the sum of the raw material monomer eventually supplied to the reactors **10** and **20** and the raw material monomer additionally supplied to the reactor **20**.

In addition to the raw material monomer and the polymerization initiator described above, any appropriate other component(s), for example, a chain transfer agent, a mold release agent, a rubbery polymer such as butadiene and styrene-butadiene rubber (SBR), a thermal stabilizing agent, and an ultraviolet absorbing agent may be used. The chain transfer agent is used for adjusting a molecular weight of a produced polymer. The mold release agent is used for improving moldability (or processability) of a resin composition obtained from the polymer composition. The thermal stabilizing agent is used for preventing a produced polymer from thermal degradation. The ultraviolet absorbing agent is used for preventing a produced polymer from being degraded by ultraviolet rays.

As to the chain transfer agent, either monofunctional or polyfunctional chain transfer agent can be used. More specifically, examples thereof include alkyl mercaptans such as n-propyl mercaptan, isopropyl mercaptan, n-butyl mercaptan, t-butyl mercaptan, n-hexyl mercaptan, n-octyl mercaptan, 2-ethylhexyl mercaptan, n-dodecyl mercaptan, and t-dodecyl mercaptan; aromatic mercaptans such as phenyl mercaptan and thiocresol; mercaptans having 18 or less carbons such as ethylene thioglycol; polyalcohols such as ethylene glycol, neopentyl glycol, trimethylolpropane, pentaerythritol, dipentaerythritol, tripentaerythritol, and sorbitol; those of which hydroxyl group is esterified with thioglycolic acid or 3-mercaptopropionic acid, 1,4-dihydronaphthalene, 1,4,5,8-tetrahydronaphthalene, terpinene, terpinolene, 1,4-cyclohexadiene, hydrogen sulfide and so on. These may be used alone or in combination of at least two of them.

The supply amount of the chain transfer agent is not particularly limited since it varies depending on the kind of the chain transfer agent used and so on. For example, in a case of using mercaptans, it is preferably 0.01 to 3% by weight, and more preferably 0.05 to 1% by weight with respect to the raw material monomer (the raw material monomer eventually supplied to the reactors **10** and **20**).

Examples of the mold release agents are not particularly limited, but include esters of higher fatty acids, higher fatty alcohols, higher fatty acids, higher fatty acid amides, metal salts of higher fatty acids and so on. As the mold release agent, one or more kinds thereof may be used.

Examples of the esters of higher fatty acids specifically include, for example, saturated fatty acid alkyl esters such as methyl laurate, ethyl laurate, propyl laurate, butyl laurate, octyl laurate, methyl palmitate, ethyl palmitate, propyl palmitate, butyl palmitate, octyl palmitate, methyl stearate, ethyl stearate, propyl stearate, butyl stearate, octyl stearate, stearyl stearate, myristyl myristate, methyl behenate, ethyl behenate, propyl behenate, butyl behenate, octyl behenate; unsaturated fatty acid alkyl esters such as methyl oleate, ethyl oleate, propyl oleate, butyl oleate, octyl oleate, methyl linoleate, ethyl linoleate, propyl linoleate, butyl linoleate, octyl linoleate; saturated fatty acid glycerides such as lauric monoglyceride, lauric diglyceride, lauric triglyceride, palm-

itic monoglyceride, palmitic diglyceride, palmitic triglyceride, stearic monoglyceride, stearic diglyceride, stearic triglyceride, behenic monoglyceride, behenic diglyceride, behenic triglyceride; unsaturated fatty acid glycerides such as oleic monoglyceride, oleic diglyceride, oleic triglyceride, linolic monoglyceride, linolic diglyceride, linolic triglyceride. Among them, methyl stearate, ethyl stearate, butyl stearate, octyl stearate, stearic monoglyceride, stearic diglyceride, stearic triglyceride, and son on are preferred.

Examples of the higher fatty alcohols specifically include, for example, saturated fatty (or aliphatic) alcohols such as lauryl alcohol, palmityl alcohol, stearyl alcohol, isostearyl alcohol, behenyl alcohol, myristyl alcohol, cetyl alcohol; unsaturated fatty (or aliphatic) alcohols such as oleyl alcohol, linolyl alcohol. Among them, stearyl alcohol is preferred.

Examples of the higher fatty acids specifically include, for example, saturated fatty acids such as caproic acid, caprylic acid, capric acid, lauric acid, myristic acid, palmitic acid, stearic acid, arachidic acid, behenic acid, lignoceric acid, 12-hydroxyoctadecanoic acid; unsaturated fatty acids such as palmitoleic acid, oleic acid, linoleic acid, linolenic acid, cetoleic acid, erucic acid, ricinoleic acid.

Examples of the higher fatty acid amides specifically include, for example, saturated fatty acid amides such as lauric acid amide, palmitic acid amide, stearic acid amide, behenic acid amide; unsaturated fatty acid amides such as oleic acid amide, linoleic acid amide, erucic acid amide; amides such as ethylene-bis-lauric acid amide, ethylene-bis-palmitic acid amide, ethylene-bis-stearic acid amide, N-oleyl stearamide. Among them, stearic acid amide and ethylene-bis-stearic acid amide are preferred.

Examples of the metal salts of higher fatty acids include, for example, sodium salts, potassium salts, calcium salts and barium salts of the above-described higher fatty acids, and so on.

A used amount of the mold release agent is preferably adjusted in a range from 0.01 to 1.0 part by weight, and more preferably adjusted in a range from 0.01 to 0.50 part by weight, with respect to 100 parts by weight of a polymer contained in a polymer composition to be obtained.

Examples of the thermal stabilizing agent are not particularly limited, but include, for example, phosphorous-based thermal stabilizing agent and organic disulfide compounds. Among them, the organic disulfide compounds are preferable. As the thermal stabilizing agent, one or more kinds thereof may be used.

Examples of the phosphorus-based thermal stabilizing agent include, for example, tris(2,4-di-*t*-butylphenyl)phosphite, 2-[[2,4,8,10-tetrakis(1,1-dimethylethyl)dibenzo[d,f][1,3,2]dioxaphosphepine-6-yl]oxy]-N,N-bis[2-[[2,4,8,10-tetrakis(1,1-dimethylethyl)dibenzo[d,f][1,3,2]dioxaphosphepine-6-yl]oxy]-ethyl]ethanamine, diphenyl tridecyl phosphite, triphenyl phosphite, 2,2-methylenebis(4,6-di-*tert*-butylphenyl)octylphosphite, bis(2,6-di-*tert*-butyl-4-methylphenyl)pentaerythritol diphosphite, and so on. Among them, 2,2-methylenebis(4,6-di-*tert*-butylphenyl)octylphosphite is preferred.

Examples of the organic disulfide compounds include, for example, dimethyl disulfide, diethyl disulfide, di-*n*-propyl disulfide, di-*n*-butyl disulfide, di-*sec*-butyl disulfide, di-*tert*-butyl disulfide, di-*tert*-amyl disulfide, dicyclohexyl disulfide, di-*tert*-octyl disulfide, di-*n*-dodecyl disulfide, di-*tert*-dodecyl disulfide, and so on. Among them, di-*tert*-alkyl disulfide is preferred, and di-*tert*-dodecyl disulfide is more preferred.

A used amount of the thermal stabilizing agent is preferably 1-2,000 ppm by weight with respect to a polymer contained in a polymer composition to be obtained. On molding

a polymer composition (more specifically, a resin composition after devolatilization) to prepare a molded article from the polymer composition of the present invention, a molding temperature is set at a higher temperature for the purpose of improving its molding processability in some cases. Use of the thermal stabilizing agent is effective for such case.

As the kinds of the ultraviolet absorbing agent, a benzophenone-based ultraviolet absorbing agent, a cyanoacrylate-based ultraviolet absorbing agent, a benzotriazole-based ultraviolet absorbing agent, a malonic ester-based ultraviolet absorbing agent, an oxalic anilide-based ultraviolet absorbing agent and so on are exemplified. These ultraviolet absorbing agents may be used alone or in combination of at least two of them. Among them, the benzotriazole-based ultraviolet absorbing agent, the malonic ester-based ultraviolet absorbing agent, and the oxalic anilide-based ultraviolet absorbing agent are preferable.

Examples of the benzophenone-based ultraviolet absorbing agent include, for example, 2,4-dihydroxybenzophenone, 2-hydroxy-4-methoxybenzophenone, 2-hydroxy-4-methoxybenzophenone-5-sulfonic acid, 2-hydroxy-4-octyloxybenzophenone, 4-dodecyloxy-2-hydroxybenzophenone, 4-benzyloxy-2-hydroxybenzophenone, 2,2'-dihydroxy-4,4'-dimethoxybenzophenone, and so on.

Examples of the cyanoacrylate-based ultraviolet absorbing agent include, for example, ethyl 2-cyano-3,3-diphenylacrylate, 2-ethylhexyl 2-cyano-3,3-diphenylacrylate, and so on.

Examples of the benzotriazole-based ultraviolet absorbing agent include, for example, 2-(2-hydroxy-5-methylphenyl)-2H-benzotriazole, 5-chloro-2-(3,5-di-*tert*-butyl-2-hydroxyphenyl)-2H-benzotriazole, 2-(3-*tert*-butyl-2-hydroxy-5-methylphenyl)-5-chloro-2H-benzotriazole, 2-(3,5-di-*tert*-pentyl-2-hydroxyphenyl)-2H-benzotriazole, 2-(3,5-di-*tert*-butyl-2-hydroxyphenyl)-2H-benzotriazole, 2-(2H-benzotriazole-2-yl)-4-methyl-6-(3,4,5,6-tetrahydrophthalimidylmethyl)phenol, 2-(2-hydroxy-5-*tert*-octylphenyl)-2H-benzotriazole, and so on.

As to the malonic ester-based ultraviolet absorbing agent, 2-(1-aryl alkylidene)malonates are generally used, and examples thereof include dimethyl 2-(*p*-methoxybenzylidene)malonate and so on.

As to the oxalic anilide-based ultraviolet absorbing agent, 2-alkoxy-2'-alkyloxalic anilides are generally used, and examples thereof include 2-ethoxy-2'-ethyloxalic anilide and so on.

A used amount of the ultraviolet absorbing agent is preferably 5-1,000 ppm by weight with respect to a polymer contained in a polymer composition to be obtained.

In the raw material monomer tank 1, the raw material monomer (one kind or a mixture of two or more kinds) as described above is appropriately prepared (together with other component(s) such as the chain transfer agent as the case may be). Further, in the raw material monomer tank 2, the raw material monomer (one kind or a mixture of two or more kinds) as described above is appropriately prepared (together with other component(s) such as the chain transfer agent as the case may be). The raw material monomer tank 2 may store the raw material monomer alone or may further comprise other component(s) such as the chain transfer agent. With respect to the raw material monomer tank 2 and the secondary line 15', a temperature of the raw material monomer stored in the raw material monomer tank 2 and/or a temperature of the raw material monomer flowing through an inside of the secondary line 15' is adjusted by the temperature regulating means such as the jacket covering at least partially the raw material monomer tank 2, the jacket covering at least partially the secondary line 15', the heater/cooler with which

19

a part of the secondary line 15' is replaced, and/or the trace pipe through which a cooling medium passes. When the raw material monomer tank 2 is provided with the jacket as the temperature regulating means, it is preferable to stir the raw material monomer in the raw material monomer tank 2 since it makes the temperature regulation more effective. Degree of the temperature regulation is appropriately adjusted depending on the desired temperature for the raw material monomer to be supplied from the secondary line to the connection line 15. In the polymerization initiator tank 3, the polymerization initiator as described above is appropriately prepared with the raw material monomer if necessary (together with other component(s) such as the chain transfer agent as the case may be). The polymerization initiator tank 3 may store the polymerization initiator alone or in the form of the mixture of the raw material monomer and the polymerization initiator (may further comprise other component(s) such as the chain transfer agent as the case may be). In a case of using the polymerization initiator tank 17, in the polymerization initiator tank 17, the polymerization initiator as described above is appropriately prepared with the raw material monomer if necessary (together with other component(s) such as the chain transfer agent as the case may be). The polymerization initiator tank 17 may store the polymerization initiator alone or in the form of the mixture of the raw material monomer and the polymerization initiator (may further comprise other component(s) such as the chain transfer agent as the case may be). However, in a case where the polymerization initiator tank 17 is connected to the supply port 21c via the pump 19, storing of the polymerization initiator alone raises a concern of local proceeding of the polymerization reaction in the reactor 20 since the polymerization initiator is solely supplied to the reactor 20. On the contrary, storing in the form of the mixture of the raw material monomer and the polymerization initiator is able to solve such concern since the polymerization initiator is mixed with a part of the raw material monomer beforehand. When the polymerization initiator tank 17 is used, it is preferable to adjust a temperature of the polymerization initiator or the mixture of the raw material monomer and the polymerization initiator (which may further comprise other component(s) such as the chain transfer agent as the case may be) by the temperature regulating means such as a jacket covering at least partially the polymerization initiator tank 17, a heater/cooler with which a part of the line between the polymerization initiator tank 17 and the supply port 21a or said another supply port 21c of the second reactor 20 is replaced, and/or a trace pipe through which a cooling medium passes. When the polymerization initiator tank 17 is provided with the jacket as the temperature regulating means, it is preferable to stir the polymerization initiator or the mixture of the raw material monomer and the polymerization initiator (which may further comprise other component(s) such as the chain transfer agent as the case may be) in the polymerization initiator tank 17 since it makes the temperature regulation more effective.

First Polymerization Step

The raw material monomer and the polymerization initiator are continuously supplied to the first reactor 10 through the supply port 11a from the raw material monomer tank 1 and the polymerization initiator tank 3 as the supply source(s) of the raw material monomer and the polymerization initiator. More specifically, the raw material monomer is continuously supplied from the raw material monomer tank 1 by the pump 5, and the polymerization initiator (preferably, the mixture of the raw material monomer and the polymerization initiator, which is also simply referred to as the polymerization initiator herein) is supplied from the polymerization initiator tank 3 by the pump 7, and they merge together through the raw

20

material supply line 9 into the first reactor 10 via the supply port 11a. Also, the polymerization initiator may be supplied from the polymerization initiator tank 3 by the pump 7 to the first reactor 10 via the supply port 11c as shown by the dotted line in FIG. 1.

For supplying the polymerization initiator to the first reactor 10, when the mixture of the raw material monomer and the polymerization initiator is prepared in the polymerization initiator tank 3 and supplied therefrom, it is preferable to adjust a ratio A:B in a range from 80:20 to 98:2 wherein A represents the supply flow rate (kg/h) of the raw material monomer from the raw material monomer tank 1, and B represents the supply flow rate (kg/h) of the mixture of the raw material monomer and the polymerization initiator (of which content ratio of the polymerization initiator is 0.002 to 10% by weight) from the polymerization initiator tank 3.

The temperature of the raw material monomer and the polymerization initiator supplied to the first reactor 10 is not particularly limited. However, this is one of factors which may change the polymerization temperature by losing a heat balance in the reactor, and therefore it is preferable to adjust that temperature appropriately by a heater/cooler (not shown in the drawings) before the supply to the reactor 10.

The raw material monomer and the polymerization initiator supplied to the first reactor 10 as described in the above are subjected to continuous polymerization, continuous bulk polymerization in this embodiment (in other words, polymerization with no solvent). This first polymerization step has only to proceed the polymerization reaction partway, and an intermediate composition is continuously taken from the effluent port 11b of the first reactor 10.

In the first polymerization step, the continuous polymerization can be conducted under a condition in which the reactor is filled with the reaction mixture while substantially no gas phase is present (hereinafter referred to as a fully filled condition). This is especially suitable for the continuous bulk polymerization. The fully filled condition can prevent beforehand the problems such as that gel adheres to and grows on the inner surface of the reactor, and that this gel is immixed into the reaction mixture to degrade quality of a polymer composition obtained in the end. Further, the fully filled condition enables all of the inner volume of the reactor to be used as a reaction space, and thereby a high productivity can be attained.

By locating the effluent port 11b of the first reactor 10 at the reactor's top as in this embodiment, the fully filled condition is conveniently realized simply by conducting the supply to and the taking from the first reactor 10, continuously. It is suitable for continuous polymerization of a methacrylic ester monomer that the effluent port is located at the reactor's top.

Further in the first polymerization step, the continuous polymerization may be conducted under the adiabatic condition (condition with substantially no heat transfer to or from outside of the reactor). This is especially suitable for the continuous bulk polymerization. The adiabatic condition can prevent beforehand the problems such as that gel adheres to and grows on the inner surface of the reactor, and that this gel is immixed into the reaction mixture to degrade quality of a polymer composition obtained in the end. Further, the adiabatic condition enables the polymerization reaction to become stable, and self regulating characteristics for suppressing a runaway reaction can be brought about.

The adiabatic condition can be realized by making the temperature of the inside of the first reactor 10 and the temperature of the outer surface thereof generally equal to each other. More specifically, this can be realized, with the use of the above described control means (not shown in the draw-

ings), by adjusting the supply amounts of the raw material monomer and the polymerization initiator to the first reactor 10 with operating the pumps 5 and 7 such that the temperature of the outer surface of the first reactor 10 set for the jacket (temperature regulating means) 13 and the temperature in the first reactor 10 detected by the temperature sensor (temperature detecting means) T correspond to each other. It is not preferable to set the temperature of the outer surface of the reactor much higher than the temperature in the reactor since it adds extra amount of heat into the reactor. The smaller the difference between the temperature in the reactor and the temperature of the outer surface of the reactor is, the better it is. More specifically, it is preferable to adjust the temperature difference within the range of $\pm 5^\circ\text{C}$.

The heat generated in the first reactor 10 such as polymerization heat and stirring heat is generally carried away on taking the intermediate composition from the first reactor 10. The amount of the heat carried away by the intermediate composition is determined by the flow rate and the specific heat of the intermediate composition, and the temperature of the polymerization reaction.

The temperature of the continuous polymerization in the first polymerization step is understood as the temperature in the first reactor 10 (detected by the temperature sensor T). The first polymerization step is conducted, for example, at a temperature in the range of 120 to 150°C ., more preferably at a temperature in the range of 130 to 150°C . It is noted, however, that the temperature in the reactor may change according to various conditions until it reaches a static state.

The pressure of the continuous polymerization in the first polymerization step is understood as the pressure in the first reactor 10. This pressure is a pressure not less than a vapor pressure of the raw material monomer at the temperature in the reactor to prevent gas of the raw material monomer from generating in the reactor, and is generally about 1.0 to 2.0 MPa in gauge pressure.

A time period subjected to the continuous polymerization in the first polymerization step is understood as an average residence time in the first reactor 10. The average residence time in the first reactor 10 can be set according to the productivity of the polymer in the intermediate composition and so on, and is not particularly limited, but, for example, from 15 minutes to 6 hours. The average residence time in the first reactor 10 can be adjusted by using the pumps 5 and 7 to change the supply amount (supply flow rate) of the raw material monomer or the like to the first reactor 10. However, since the average residence time depends in a large part on the inner volume of the first reactor 10, how the inner volume of the first reactor 10 and the inner volume of the second reactor 20 are designed is important as hereinafter described.

As described in the above, the intermediate composition is continuously taken from the effluent port 11b of the first reactor 10. The obtained intermediate composition comprises the generated polymer and the unreacted raw material monomer, and may further comprise the unreacted polymerization initiator, decomposed substance of the polymerization initiator, and so on.

Although this embodiment is not limited thereto, the polymerization ratio in the intermediate composition is, for example, 5 to 80% by weight. The polymerization ratio in the intermediate composition generally corresponds to the content ratio of the polymer in the intermediate composition.

Intermediate Cooling Step

The intermediate composition obtained as described in the above is continuously taken from the effluent port 11b of the first reactor 10 and flows inside the connection line 15. On the other hand, the raw material monomer is continuously sup-

plied from the raw material monomer tank 2 through the secondary line 15' into the connection line 15 via the combining part M. More specifically, the raw material monomer (the mixture of the raw material monomer and other component(s) such as the chain transfer agent as the case may be) is continuously supplied from the raw material monomer tank 2 through the secondary line 15' to the connection line 15 via the combining part M by the pump 6. At the combining part M, the raw material monomer supplied from the secondary line 15' is added to the intermediate composition flowing from the effluent port 11b of the first reactor 10, and they flow together inside the connection line 15 to the supply port 21a of the second reactor 20. Thereby, the intermediate composition (more specifically, the mixture of the original intermediate composition taken from the first reactor and the raw material monomer added thereto) is supplied to the second reactor 20 through the supply port 21a, continuously.

It is preferable to make a ratio N:C within a range from 0.995:0.005 to 0.5:0.5 wherein N represents the flow rate (kg/h) of the intermediate composition taken from the effluent port 11b of the first reactor 10 to the connection line 15 (the original intermediate composition), and C represents the flow rate (kg/h) of the raw material monomer supplied from the secondary line 15' to the connection line 15. If the flow rate C of the raw material monomer is too small, sufficient cooling effect on the intermediate composition is likely to be impaired. If the flow rate C of the raw material monomer is too large, a ratio of unreacted raw material monomer in the polymer composition taken from the second reactor 20 is increased and this tends to put a larger load on the recycle system, and/or the residence time in the second reactor 20 is shortened, so that the more amount of polymerization initiator is required for attaining the desired productivity and thereby thermal stability of the polymer obtained is likely to be lowered.

The addition to the intermediate composition taken from the effluent port 11b of the first reactor 10 (the original intermediate composition) with the raw material monomer having a temperature lower than that of this intermediate composition results in cooling of the intermediate composition. In other words, the temperature of the intermediate composition obtained thereafter is lower than that of the original intermediate composition. Such cooling can be conducted so as to make the temperature of the intermediate composition in the supply port 21a of the second reactor 20 lower, e.g. 5 – 80°C ., lower, than the temperature of the intermediate composition in the effluent port 11b of the first reactor 10. The raw material, which can be used, has a temperature of, for example, -40 to 30°C ., and preferably -40 to 10°C . at the time point of being supplied to the connection line 15 from the secondary line 15'. If the temperature is too low, some kinds of the raw material monomer become coagulated, so that the secondary line 15' is likely to be obstructed. If the temperature is too high, on the other hand, sufficient cooling effect on the intermediate composition is likely to be impaired. When the polymerization initiator tank 17 is connected to the connection line 15 via the pump 19, it is also possible to cool the intermediate composition by adding the polymerization initiator or the mixture of the raw material monomer and the polymerization initiator (which may further comprise other component(s) such as the chain transfer agent as the case may be) supplied to the intermediate composition from the polymerization initiator tank 17. The polymerization initiator or the mixture of the raw material monomer and the polymerization initiator, which can be used, has a temperature of, for example, -40 to 30°C ., and preferably -40 to 10°C . at the time point of being supplied to the connection line 15.

In the case of the combination use with the cooling means as in the embodiment of FIG. 2 or FIG. 3, the intermediate composition is continuously cooled between the effluent port 11b of the first reactor 10 and the supply port 21a of the second reactor 20 by the jacket 16 or the cooler 40 which is a cooling means provided to the connection line 15. In this case, the temperature of the raw material monomer supplied from the secondary line 15' is adjusted in a temperature range which is lower than the temperature of the intermediate composition in the connection line 15 just before the combining point with the secondary line 15'. Such adjustment can be conducted so as to make the temperature of the intermediate composition in the supply port 21a of the second reactor 20 lower, e.g. 5-80° C. lower, than the temperature of the intermediate composition in the effluent port 11b of the first reactor 10. The raw material, which can be used, has a temperature of, for example, -40 to 30° C., and preferably -40 to 10° C. at the time point of being supplied to the connection line 15 from the secondary line 15'.

Further, it is not necessary for the present invention, but it is preferable to provide the connection line 15 with a mixing means. By providing with the mixing means, the intermediate composition flowing in the connection line 15 is homogeneously mixed. As a result, a temperature distribution tends to be homogenized, and an occlusion of the connection line 15 by the intermediate composition can be suppressed. When the connection line 15 is provided with the mixing means, the connection line 15 may be provided with a static mixer or a dynamic mixer, or the connection line 15 may be provided with the cooler 40 which combines a mixing means and a cooling means.

Degree of cooling may be varied depending on difference between the temperature in the first reactor 10 and the temperature in the second reactor 20, and so on, for example, as in the preferable example of the control described in the above. The degree of cooling is adjusted depending on the desired polymerization temperature and polymerization ratio in the second reactor 20, specifically, the cooling can be conducted so that the temperature of the intermediate composition in the supply port 21a of the second reactor 20 become, for example, 5 to 80° C. lower temperature than the temperature of the intermediate composition in the effluent port 11b of the first reactor 10.

Second Polymerization Step

The second polymerization step is conducted in series with and following to the first polymerization step.

After the intermediate composition cooled by being passed through the connection line 15 as described in the above is supplied to the second reactor 20 from the supply port 21a. Then, the intermediate composition is further subjected to continuous polymerization, continuous bulk polymerization in this embodiment in the second reactor 20. This second polymerization step is to let the polymerization reaction proceed to the desired polymerization ratio, and a polymer composition (or polymerization syrup) is continuously taken from the effluent port 21b of the second reactor 20.

Hereinafter, the second polymerization step will be described mainly with respect to different points from the first polymerization step, and explanations similar to those for the first polymerization step apply unless otherwise explained.

Although it is not necessary to this embodiment, but it is preferable to use the polymerization initiator tank 17 and the pump 19. In a case of using the polymerization initiator tank 17 and the pump 19, the additional (or fresh) polymerization initiator (preferably, the mixture of the raw material monomer and the polymerization initiator) is supplied from the polymerization initiator tank 17 by the pump 19 through the

connection line 15 to the second reactor 20 via the supply port 21a or the another supply port 21c, and thereby the additional polymerization initiator is added to the intermediate composition.

Further, cooling the intermediate composition taken from the first reactor by adding the raw material monomer from the secondary line 15' and by using the jacket 16 or the cooler 40 which may be provided to the connection line 15 as a cooling means before supplying it to the second reactor, even if a polymerization heat is generated in the second reactor 20, it is possible to conduct continuous polymerization with avoiding generation of a temperature inhomogeneous state in the second reactor 20, and to achieve a high polymerization ratio with retain a low temperature in the second reactor 20, that is, to increase a productivity of the polymer. As a result, it is possible to effectively produce the polymer composition having superior thermal stability and heat resistance. Further, keeping a supply temperature of the intermediate composition to the second reactor 20 constant by adjusting the supply temperature by adding the raw material monomer from the secondary line 15' and by using the jacket 16 or the cooler 40 which may be provided to the connection line as a cooling means, it is possible to more stably conduct continuous polymerization in the second polymerization step.

For supplying the polymerization initiator to the second reactor 20, when the mixture of the raw material monomer and the polymerization initiator is prepared in the polymerization initiator tanks 3 and 17 and supplied therefrom, it is preferable to adjust a ratio (A+B1+C):B2 in a range from 80:20 to 98:2 and a ratio B1:B2 in a range from 10:90 to 90:10 wherein A represents the supply flow rate (kg/h) of the raw material monomer from the raw material monomer tank 1, C represents the supply flow rate (kg/h) of the raw material monomer from the secondary line 15' to the connection line 15, B1 represents the supply flow rate (kg/h) of the mixture of the raw material monomer and the polymerization initiator (of which content ratio of the polymerization initiator is 0.002 to 10% by weight) from the polymerization initiator tank 3, and B2 represents a supply flow rate (kg/h) of the mixture of the raw material monomer and the polymerization initiator (of which content ratio of the polymerization initiator is 0.002 to 10% by weight) from the polymerization initiator tank 17.

Also, in the second polymerization step, the continuous polymerization can be conducted under a fully filled condition. This is especially suitable for the continuous bulk polymerization. The fully filled condition can prevent beforehand the problems such as that gel adheres to and grows on the inner surface of the reactor, and that this gel is immixed into the reaction mixture to degrade quality of the polymer composition obtained in the end. Further, the fully filled condition enables all of the inner volume of the reactor to be used as a reaction space, and thereby a high productivity can be attained.

By locating the effluent port 21b of the second reactor 20 at the reactor's top as in this embodiment, the fully filled condition is conveniently realized simply by continuously conducting the supply to and the taking from the second reactor 20, continuously. It is suitable for continuous polymerization of a methacrylic ester monomer that the effluent port is located at the reactor's top.

Also, further in the second polymerization step, the continuous polymerization may be conducted under the adiabatic condition. This is especially suitable for the continuous bulk polymerization. The adiabatic condition can prevent beforehand the problems such as that gel adheres to and grows on the inner surface of the reactor, and that this gel is immixed into the reaction mixture to degrade quality of the polymer com-

position obtained in the end. Further, the adiabatic condition enables the polymerization reaction to become stable, and self-regulating characteristics for suppressing a runaway reaction can be brought about.

The adiabatic condition can be realized by making the temperature of the inside of the second reactor **20** and the temperature of the outer surface thereof generally equal to each other. More specifically, this can be realized, with the use of the above described control means (not shown in the drawings), by adjusting the supply amounts of the raw material monomer and the polymerization initiator to the second reactor **20** with operating the pumps **5-7** and, if present, the pump **19** such that the temperature of the outer surface of the second reactor **20** set for the jacket (temperature regulating means) **23** and the temperature in the second reactor **20** detected by the temperature sensor (temperature detecting means) **T** correspond to each other. It is not preferable to set the temperature of the outer surface of the reactor much higher than the temperature in the reactor since it adds extra amount of heat into the reactor. The smaller the difference between the temperature in the reactor and the temperature of the outer surface of the reactor is, the better it is. More specifically, it is preferable to adjust the temperature difference within the range of $\pm 5^{\circ}\text{C}$.

The heat generated in the second reactor **20** such as polymerization heat and stirring heat is generally carried away on taking the polymer composition from the second reactor **20**. The amount of the heat carried away by the polymer composition is determined by the flow rate and the specific heat of the polymer composition, and the temperature of the polymerization reaction.

The temperature of the continuous polymerization in the second polymerization step is understood as the temperature in the second reactor **20**. The second polymerization step is conducted, for example, at a temperature in the range of 120 to 150°C ., more preferably at a temperature in the range of 130 to 150°C . It is preferable to adjust the temperature in the second polymerization step so that temperature difference from the temperature of the continuous polymerization in the first polymerization step falls within 10°C . In the second polymerization step, though the temperature may be increased by polymerization heat generated in the polymerization reaction, it is possible to reduce difference between the temperature in the first polymerization step and the temperature in the second polymerization step by the intermediate cooling. As a result, the thermal stability and heat resistance is improved compared with when the polymerization is conducted at a lower temperature in the first reactor, then the polymerization is conducted at a higher temperature in the second reactor.

The pressure of the continuous polymerization in the second polymerization step is understood as the pressure in the second reactor **20**. This pressure is generally about 1.0 to 2.0 MPa in gauge pressure, and may be equal to the pressure in the first polymerization step.

A time period subjected to the continuous polymerization in the second polymerization step is understood as an average residence time in the second reactor **20**. The average residence time in the second reactor **20** can be set according to the productivity of the polymer in the polymer composition and so on, and is not particularly limited, but, for example, from 15 minutes to hours. A ratio of the average residence time in the second reactor **20** to the average residence time in the first reactor **10** is preferably from $9/1$ to $1/9$, and more preferably from $8/2$ to $2/8$. The average residence time in the second polymerization step may be equal to the average residence time in the first polymerization step, but preferably different

from it. The average residence time in the second reactor **20** can be adjusted by using the pumps **5-7** and, if present, the pump **19** to change the supply amount (supply flow rate) of the raw material monomer or the like to the second reactor **20**. However, since the average residence time depends in a large part on the inner volume of the second reactor **20**, how the inner volume of the first reactor **10** and the inner volume of the second reactor **20** are designed is important as hereinafter described.

As described in the above, the polymer composition is continuously taken from the effluent port **21b** of the second reactor **20**. The obtained polymer composition comprises the generated polymer, and may further comprise the unreacted raw material monomer, the unreacted polymerization initiator, decomposed substance of the polymerization initiator, and so on.

Although this embodiment is not limited thereto, the polymerization ratio in the polymer composition is, for example, 30 to 90% by weight. The polymerization ratio in the polymer composition generally corresponds to the content ratio of the polymer in the polymer composition. The higher the polymerization ratio, the higher the productivity of the polymer, but also the higher the viscosity of the composition from intermediate composition to the polymer composition, resulting in the larger the necessary power for stirring. The lower the polymerization ratio, the lower the productivity of the polymer, resulting in the larger the load for recovering the unreacted raw material monomer. Therefore, it is preferable to set an appropriate polymerization ratio as a target or a guide.

According to this embodiment, in order to achieve the desired polymerization ratio and low polymerization temperature in the second reactor **20**, simultaneously, the addition of the raw material monomer from the secondary line and, in the case of the combination use, the control of the cooling means of the connection line are conducted so as to make the temperature in the connection line adjacent to the supply port of the second reactor lower than the temperature in the first reactor detected by the temperature detecting means of the first reactor, thereby it is possible to cool the intermediate composition at high efficiency and to produce the polymer composition having superior thermal stability and heat resistance with high productivity.

In general, the following tendency is observed: the higher the polymerization temperature, the lower the syndiotacticity of the obtained polymer, the lower the heat resistance of a resin composition obtained in the end. Therefore, it is preferable to conduct a polymerization at a low temperature to obtain a resin composition having high heat resistance. However, if continuous polymerization is conducted in one stage only at a lower temperature with the use of the conventional continuous polymerization apparatus (Patent Literatures 1 and 2), a long time is required to achieve the desired polymerization ratio. Therefore, it requires a larger reactor, furthermore larger space to realize a longer average residence time, so that it is not efficient. In addition, when the average residence time is longer than necessary, the generation of the oligomer such as a dimer and trimer is increased, thereby a concern of decreasing the heat resistance of the resin obtained from the polymer composition is raised.

In addition, the amount of the polymerization initiator can be set depending on other factors such as a polymerization temperature, a desired polymerization ratio, and an average residence time, and so on. The lower the polymerization temperature or the shorter the average residence time, the larger the amount of the polymerization initiator required for achieving the desired polymerization ratio. However, the

larger the amount of the polymerization initiator, the larger the remained amount of the terminal part which consists of an unstable unsaturated bond and at which polymerization is stopped (terminal polymer) in the polymer composition, as a result, the thermal stability of the resin composition finally obtained tends to be decreased. Also, the much higher the polymerization temperature, the larger the generated amount of the terminal part which consists of an unsaturated bond derived from the polymerization initiator and at which polymerization is stopped (terminal polymer) in the polymer composition, as a result, the thermal stability of the resin composition finally obtained tends to be decreased.

In this embodiment, for example, the continuous polymerization is conducted at the temperature in the given range (for example, 120-150° C.) in the first polymerization step, then the continuous polymerization can be further conducted at the temperature in the same range as in the first polymerization step (for example, 120-150° C.) in the second polymerization step. Specifically, a cooling step is conducted in the connection line between the first reactor and the second reactor and additional polymerization initiator is supplied to the second reactor so as to reduce the difference between the temperature of the continuous polymerization in the first polymerization step and the temperature of the continuous polymerization in the second polymerization step, and then an adiabatic polymerization can be conducted. As a result, the continuous polymerization can be effectively conducted in the smaller space compared with when it is conducted in one stage at a lower temperature, and can produce the polymer composition suitable for obtaining a resin composition which has higher heat resistance and contains lower impurities such as gel generated by an adiabatic polymerization compared with when it is conducted in one stage at a higher temperature.

Further, in this embodiment, for example, a time period subjected to the continuous polymerization in the first polymerization step can differ from a time period subjected to the continuous polymerization in the second polymerization step. Specifically, it is possible to differentiate between the first reactor and the second reactor in an average residence time by designing the reactors so as to make the inner volume of the first reactor and the inner volume of the second reactor different from each other. Further, it is possible to differentiate between the first reactor and the second reactor in an average residence time by adding additional polymerization initiator together with the raw material monomer to the second reactor. When the average residence time is increased, by controlling the residence time and the polymerization ratio in the first reactor and the second reactor, it is possible to decrease the amount of the polymerization initiator to be supplied to the reactor, thereby obtaining the polymer composition suitable for regulating the thermal stability of the whole of the resin composition to obtain the resin composition having high thermal stability.

How the polymerization reaction conditions are set for each of the first polymerization step and the second polymerization step may vary according to the polymer generated, the raw material monomer and the polymerization initiator used, the heat resistance, thermal stability and productivity desired, and so on.

Devolatilization Step

As described in the above, the polymer composition (polymerization syrup) taken from the effluent port 21b of the second reactor 20 may comprise the unreacted raw material monomer and polymerization initiator and so on, in addition to the generated polymer. Although this embodiment is not limited thereto, such polymer composition is preferably sub-

jected to, for example, devolatilization to separate and recover the raw material monomer.

More specifically, the polymer composition is transferred to the preheater 31 through the effluent line 25. The polymer composition in the preheater 31 is added with a part or all of an amount of heat necessary to volatilize the volatile component which is mainly composed of the unreacted raw material monomer. Then, the polymer composition is transferred to the devolatilizing extruder 33 via the pressure adjusting valve (not shown in the drawings), and the volatile component is at least partially removed in the devolatilizing extruder, and a residual extruded object is formed into pellets and discharged from the discharge line 35. Thereby, the resin composition comprising a methacrylic ester polymer is produced in the form of the pellets.

As a method for transferring the above polymer composition, a method described in JP 4-48802 B is preferable. As a method of using a devolatilizing extruder, methods described in, for example, JP 3-49925 A, JP 51-29914 B, JP 52-17555 B, JP 1-53682 B, JP 62-89710 A and so on are preferable.

Further, during or after devolatilization of the polymer composition in the devolatilizing extruder described above, the polymer composition or the extruded object can be added with lubricants such as higher alcohols and higher fatty acid esters, an ultraviolet absorbing agent, a thermal stabilizing agent, a colorant, an antistatic agent and so on, in order to incorporate them into the resin composition, if necessary.

The volatile component removed in the devolatilizing extruder 33 consists primarily of the unreacted raw material monomer and includes impurities; e.g. impurities originally contained in the raw material monomer, additives used if necessary, volatile by-product(s) generated in the process of polymerization, oligomer such as dimer and trimer, decomposed substance of the polymerization initiator, and so on. In general, a larger amount of the impurities make the obtained resin composition colored, which is not preferable. Then, the volatile component removed in the devolatilizing extruder 33 (which consists primarily of the unreacted raw material monomer and includes impurities as described above) may be passed through a monomer recovery column (not shown in the drawings), and treated by means of distillation, adsorption and so on in the monomer recovery column to remove the impurities from the above described volatile component. Thereby, the unreacted raw material monomer can be recovered with high purity, so that it can be suitably reused as the raw material monomer for polymerization. For example, continuous distillation is conducted in the monomer recovery column to recover the unreacted raw material monomer with high purity as a distillate liquid from the top of the monomer recovery column, and it may be transferred and recycled to the raw material monomer tank 1 after it is reserved in the recovery tank 37 once, or it may be transferred and recycled to the raw material monomer tank 1 without being reserved in the recovery tank 37. On the other hand, the impurities removed in the monomer recovery column may be disposed as a waste.

In order to prevent the recovered raw material monomer from causing the polymerization reaction in the recovery tank 37 and/or the raw material monomer tank 1, it is preferable that a polymerization inhibitor exists in the recovery tank 37 or the raw material monomer tank 1 at a ratio of, for example, 2 to 8 ppm by weight with respect to the raw material monomer, and more preferably, in addition to this, an oxygen concentration in a gas phase in the recovery tank 37 or the raw material monomer tank 1 is set at 2 to 8% by volume. If the recovered raw material monomer is wanted to be preserved in

the recovery tank 37 for a long time, it is preferable to reserve it at a low temperature of, for example, 0 to 5° C.

In this embodiment, the continuous bulk polymerization apparatus wherein the first reactor and the second reactor are both used to conduct the continuous bulk polymerization is described. However, the continuous polymerization apparatus of the present invention is not limited thereto, one or both of the first reactor and the second reactor may be used to conduct continuous solution polymerization. In such embodiment, since a solvent is used for the solution polymerization, the continuous polymerization apparatus is provided, in addition to a similar configuration to the continuous polymerization apparatus described in the above with reference to FIGS. 1-3, with a solvent tank and a supply line and a pump (supply means) associated with the solvent tank to supply the solvent to a certain reactor for conducting the solution polymerization. The solvent tank and the supply line and the pump (supply means) associated with the solvent tank are not particularly limited, those similar to conventionally used ones can be used. The solvent can be supplied to the certain reactor for conducting the solution polymerization after being mixed with the raw material monomer and/or the polymerization initiator, or can be supplied to the certain reactor for conducting the solution polymerization, directly. In the above certain reactor, the polymerization step is conducted similarly to the polymerization step described in the above with reference to FIGS. 1-3, except that the solvent is used in the polymerization reaction. As to the solvent, it is appropriately selected according to the raw material monomer of the solution polymerization reaction and so on, and not particularly limited, but examples thereof include toluene, xylene, ethyl benzene, methyl isobutyl ketone, methyl alcohol, ethyl alcohol, octane, decane, cyclohexane, decalin, butyl acetate, pentyl acetate, and so on. A ratio D:E is, for example, 70:30 to 95:5, and preferably 80:20 to 90:10, but not limited thereto, wherein D represents a supply flow rate (kg/h) of the raw material monomer to the certain reactor for conducting the solution polymerization, and E represents a supply flow rate (kg/h) of the solvent to this certain reactor.

The continuous polymerization apparatus and the process for producing the polymer composition of the present invention are hereinbefore described through the embodiment of the present invention in detail. According to the present invention, provided is a novel continuous polymerization apparatus, and when such continuous polymerization apparatus are used, since the polymerization can be conducted in at least two stages in series by using at least the first reactor and the second reactor, it is possible to set the polymerization reaction conditions, specifically, the temperature, the time period (average residence time), the amount of the polymerization initiator (a ratio of the polymerization initiator to the raw material monomer) and so on in each of the first polymerization step and the second polymerization step, respectively. Therefore, depending on the desired polymerization temperature and polymerization ratio in the second reactor, the addition of the raw material monomer from the secondary line and, in the case of the combination use, the control of the cooling means of the connection line can make the temperature in the connection line adjacent to the supply port of the second reactor lower than the temperature in the first reactor detected by the temperature detecting means of the first reactor, thereby it becomes possible to control the syndiotacticity of the polymer contained in the finally obtained resin composition to more efficiently produce the polymer composition suitable for obtaining a resin composition having high heat resistance and thermal stability.

However, the present invention is not limited to the above embodiment, and various modifications can be made. For example, three or more reactors can be used to conduct the polymerization in three or more stages in series. Further, the process for producing the polymer composition of the present invention is continuously conducted preferably by using the continuous polymerization apparatus of the present invention, but it may be conducted in a batch method.

The polymer composition produced by the process of the present invention is preferably used as a material for a molded article, and the molded article obtained therefrom has an advantage of having high heat resistance and thermal stability. For example, the polymer composition produced by the process of the present invention (more specifically, the resin composition after devolatilization) is molded alone or together with any suitable other component(s) according to any molding process such as injection molding and extrusion molding to prepare a molded article. The polymer composition produced by the process of the present invention is preferably used for preparing a molded article by injection molding, and it is possible to prepare a molded article with good moldability and prevent silver streaks from occurring. Especially, since the resin composition comprising a methacrylic ester based polymer has a superior transparency, the molded article prepared from it by injection molding has high transparency and less occurrence of silver streaks and good moldability, and therefore it is preferably utilized as a material for a light guide plate, which is used as a member of a backlight unit for various types of liquid crystal displays, or for vehicle members such as a rear lamp cover, a head lamp cover, a visor, a meter panel, and so on.

Injection molding can be conducted by filling (injecting into) a mold having a certain thickness with at least the polymer composition produced by the process of the present invention in a molten state, followed by cooling, and then thus molded article is released from the mold. More specifically, the molded article can be prepared by, for example, supplying a molding machine from a hopper with the polymer composition produced by the process of the present invention (more specifically, the resin composition after devolatilization) alone or in combination with any other suitable components, retracting and rotating a screw to measure the resin composition in a cylinder of the molding machine, melting the resin composition in the cylinder, filling a mold (e.g. metal mold) with the molten resin composition under pressure, holding the pressure for a certain time period until the mold is sufficiently cooled, opening the mold to eject the molded article therefrom.

Thus, according to another aspect of the present invention, there is also provided a molded article prepared from the polymer composition produced by the process of the present invention. It is noted that conditions for preparing the molded article of the present invention from the polymer composition (for example, in a case of injection molding, a temperature for melting a molding material, a temperature of a mold to which the molding material is injected, a pressure to be held after the mold is filled with the molding material, and so on) can be appropriately set and are not specifically limited.

INDUSTRIAL APPLICABILITY

The present invention can be used for producing a polymer composition which is suitable for obtaining a resin composition comprising a methacrylic ester polymer(s).

31

The invention claimed is:

1. A continuous polymerization apparatus which comprises, at least, a first reactor and a second reactor which are of a complete mixing type,

wherein each of the reactors is provided with a supply port, an effluent port, and a temperature detecting means for detecting a temperature in the reactor,

the supply port of the first reactor is connected to supply sources of a raw material monomer and a polymerization initiator,

the effluent port of the first reactor is connected through a connection line to the supply port of the second reactor, the connection line is combined with a secondary line for supplying a raw material monomer at a combining part located between the effluent port of the first reactor and the supply port of the second reactor, and

wherein the secondary line is connected to a source of the raw material monomer, and at least one of said source and said secondary line is provided with a temperature regulating means.

2. The continuous polymerization apparatus according to claim 1, wherein the connection line is provided with a cooling means.

3. The continuous polymerization apparatus according to claim 1, wherein the connection line is provided with a mixing means between the combining part and the supply port of the second reactor.

4. The continuous polymerization apparatus according to claim 1, wherein the effluent port of each of the reactors is placed at the top of the reactor.

5. The continuous polymerization apparatus according to claim 1, wherein the supply port of the second reactor or another supply port provided to the second reactor is connected to a supply source of an additional polymerization initiator.

6. The continuous polymerization apparatus according to claim 1, wherein the first reactor and the second reactor are used for conducting a continuous bulk polymerization.

7. A process for producing a polymer composition by using the continuous polymerization apparatus according to claim 1 which comprises:

a first polymerization step of continuously supplying a raw material monomer and a polymerization initiator from the supply sources of the raw material monomer and the

32

polymerization initiator to the first reactor though the supply port of the first reactor to be subjected to continuous polymerization in the first reactor, and continuously taking a resultant intermediate composition from the effluent port of the first reactor,

an intermediate cooling step of continuously cooling the intermediate composition by adding a raw material monomer supplied from the secondary line to the intermediate composition during transport of the intermediate composition from the effluent port of the first reactor to the supply port of the second reactor through the connection line, and

a second polymerization step of continuously supplying the cooled intermediate composition to the second reactor through the supply port of the second reactor to be further subjected to continuous polymerization in the second reactor, and continuously taking a resultant polymer composition from the effluent port of the second reactor.

8. The process for producing a polymer composition according to claim 7, wherein a temperature of the intermediate composition in the supply port of the second reactor is 5-80° C. lower than a temperature of the intermediate composition in the effluent port of the first reactor.

9. The process for producing a polymer composition according to claim 7, wherein a flow rate ratio of the intermediate composition taken out of the effluent port of the first reactor to the connection line and the raw material monomer supplied from the secondary line to the connection line is within a range from 0.995:0.005 to 0.5:0.5.

10. The process for producing a polymer composition according to claim 7, wherein a temperature of the raw material monomer supplied from the secondary line to the connection line is from -40 to 30° C.

11. The process for producing a polymer composition according to claim 7, wherein a temperature in the first reactor detected by the temperature detecting means of the first reactor and a temperature in the second reactor detected by the temperature detecting means of the second reactor are within a range from 120 to 150° C.

12. A molded article which is prepared from the polymer composition produced by the process according to claim 7.
